

1 RESEALABLE CONTAINER WITH MAGNETIC CLOSURE SYSTEM

3 BACKGROUND OF THE INVENTION

4 This invention relates to a structure and method of fabricating a resealable
5 container with a magnetic closure system.

6 Containers store, retain and preserve numerous products. Containers are made
7 from a variety of materials and are formed into many shapes and sizes. An exemplary
8 conventional container is a cereal box made from paperboard. Generally, after placing a
9 product in a container the container is closed. Containers designed for "one time" use
10 generally do not have a re-closure system. However containers that dispense a product at
11 intermittent intervals, such as cereal boxes, generally require a re-closure system.

12 Conventional re-closure systems include an arrangement of opposing flaps on the
13 container, for example at the top of a container. In a "tab and slot" system a tab
14 extending from a first flap of the container is tucked into a slot located on an opposing
15 flap. The tab and slot secure the opposing flaps in a closed position.

16 The aforementioned conventional container "tab and slot" re-closure system
17 works well mechanically so long as the initial opening of the container does not tear or
18 deform the container flaps or tab. The ease of initially opening the container depends
19 upon the strength of the bonds that holds the opposing container flaps together.

20 Conventionally, opposing flaps are secured to each other by various adhesive
21 compounds. The type and amount of adhesive used is chosen to balance the strength of
22 the container's initial seal with the ease of initially separating the opposing flaps from
23 each other. A major deficiency with the conventional "tab and slot" re-closure system is

1 that after opening, the re-closure system does not provide an acceptable container barrier,
2 especially for food or perishables items.

3 To address this shortcoming, perishable items are conventionally placed in a in an
4 air, moisture, and vermin barrier, hereinafter referred to as "membrane." The membrane
5 is vacuum sealed before the container is closed. For example, food products, such as
6 cereal, crackers, biscuits, and cookies are conventionally sealed in a separate membrane
7 before the container is initially sealed. The membrane serves to protect the product prior
8 to the initial opening of the container and provides additional barrier protection after the
9 container is open. Membrane materials typically comprise plastic, foil, or paper that has
10 been laminated or coated to produce the desired barrier properties, such as air, moisture,
11 and vermin control.

12 The integrity of the membrane and the available time interval for safely
13 consuming the membrane's product depends directly upon the care with which the
14 membrane was initially opened as well as the care with which the membrane is re-closed
15 after each opening. A typical membrane is re-closed by rolling the membrane from the
16 top until the roll is tight against the product. Additional methods include clipping or
17 otherwise securing the rolled up membrane to eliminate unrolling. A main disadvantage
18 of the "rolling" method is that it requires attention and care by the user. In addition, the
19 rolling method often fails to produces an adequate seal for perishable products even when
20 the user rolls according to best practice. In sum, conventional membrane re-closure
21 techniques do not adequately protect perishable products. As a result the available
22 consumption time for a product is not maximized.

1 A variety of other container re-closure systems exist. They can be classified into
2 four general categories: (1) zippers, (2) pinching aids such as metallic ties and plastic
3 clips, (3) spouts of various sorts including folding, pullout, and screw-top types, and (4)
4 various closure flap retention systems. Zippers generally include a design where a
5 container has an integrated zipper re-closure system formed in either the container or
6 membrane. Pinching aids are conventional devices typically applied to the container
7 flaps and/or membrane. An exemplary use of a pinching aid is to secure the rolled up
8 portion of a membrane. Container spout designs include the use of paperboard or plastic
9 elements secured to both containers and/or membranes that aid in removing the product
10 from the container and can be repositioned to cover a container opening.

11 Flap retention systems secure moveable flaps to cover openings in the container.
12 Conventionally flaps require the use of pressure sensitive adhesive or magnetic forces to
13 secure the flap over the opening. An exemplary flap adhesive re-closure system is
14 disclosed in U.S. Patent 4,632,299 by Albert Holmberg, entitled "Reclosable Containers."
15 It discloses a container with an opening and a closure flap to cover the opening. The
16 flap's perimeter has a pressure sensitive adhesive tape that secures the flap to the
17 container. However, a major disadvantage of the Holmberg container is the possibility
18 that debris will accumulate upon the adhesive coating causing incomplete sealing of the
19 flap to the container. In addition, after repeated openings, the adhesive coating may
20 weaken or fail, leaving the flap unsecured or partially unsecured to the container. In
21 addition, the adhesive flap re-closure system requires care and attention by the user to
22 properly secure the flap against the container.

1 An exemplary magnetic re-closure system is disclosed in U.S. Patent 4,738,390
2 by Gerald Brennan, entitled "Magnetic Closure Device For Envelope or the Like." A
3 second exemplary magnetic re-closure system is disclosed in U. S. Patent 3,749,301 by
4 George Pecker, entitled "Magnetically Sealable Container." Finally a third exemplary
5 magnetic closure system is disclosed in U. S. Patent 5,505,305 by Matthew Scholz, et. al.,
6 entitled "Moisture-Proof Resealable Pouch and Container." The three examples each rely
7 on magnetic attractive forces to secure a "flap-like" article to the container. However
8 these conventional magnetic re-closure systems either fail to provide a secure container
9 barrier for perishable items or require the use of a membrane in addition to the magnetic
10 closure system to obtain acceptable product protection.

11 In summary, conventional container re-closure systems do not achieve an easy,
12 low cost, and reliable re-closure system. As a result containers with conventional re-
13 closure systems fail to provide an optimum air, moisture, and vermin barrier. In addition,
14 adding a conventional membrane internal to the container to improve product protection
15 results in increased packaging costs and fails to optimize product protection.

16 What is needed is a container with a re-closure system that provides an improved
17 container seal after initial opening that is easy to open and close, is low cost, reliable, and
18 requires little attention from the user. In addition, what is needed is a container with a re-
19 closure system that eliminates the need and cost of an internal membrane.

1 In a first exemplary embodiment, magnetic gaskets cut from commercially
2 available flexible magnetic sheet are secured to the container body and flap in the desired
3 pattern and location. The magnetic gaskets are then polarized to create magnetically
4 attractive regions.

5 In a second exemplary embodiment, magnetic regions are formed on the flap and
6 container by printing ink containing ferrite material in the desired pattern and location.
7 The ferrite regions are then polarized to create magnetically attractive regions.

8 BRIEF DESCRIPTION OF THE DRAWING

9 The above and other features of the present invention which will become more
10 apparent in the description below, and can be understood by the following detailed
11 description in conjunction with the accompanying figures, wherein like characters
12 represent like parts throughout the several view and in which:

13 Figure 1 is a plan view of a blank for a container with a top flap according to the
14 invention;

15 Figure 2 is an orthogonal view of a container formed from the blank of Figure 1;

16 Figure 3 is a plan view of a second embodiment of a blank container with a top
17 flap according to the invention;

18 Figure 4 is an orthogonal view of a container formed from the blank of Figure 2;

19 Figure 5 is a plan view of a third embodiment of a blank container with a top flap
20 according to the invention;

21 Figure 6 is an orthogonal view of a container formed from the blank of Figure 5;

1 Figure 7 is a plan view of a third embodiment of a blank container with a top flap
2 according to the invention;

3 Figure 8 is an orthogonal view of a container formed from the blank of Figure 7;

4 Figure 9 is a plan view of a blank container with a side flap according to the
5 invention;

10 11;

11

12 DETAILED DESCRIPTION OF THE INVENTION
13

14 Figure 1 illustrates an exemplary container blank or substrate 100 for forming a
15 container 105 (Figure 2) according to the invention. In an exemplary embodiment the
16 blank 100 is made from paperboard or paper. However it is to be understood that the
17 invention covers a wide range of suitable materials for blank 100 including various
18 plastic compositions and laminates.

19 In an exemplary embodiment, blank comprises four bottom sections, 170, 172,
20 174, 176, four main body sections 130, 132, 134, 136, and four top sections 150, 152,
21 153, 154. The blank 100 has a plurality of fold lines 104, 106, 108. The blank 100

1 sections are folded and cut to form container 105 (Figure 2). Glue flap 160 is one means
2 to secure the folded main body sections 130, 132, 134 in the shape of a conventional
3 container shape. Bottom sections 170, 172, 174, 176 and top sections 150, 152, 153, 154
4 are cut and folded to form a closeable top and bottom for the container 105. Top section
5 153 provides a glue flap to provide integrity to the container.

6 An aperture 140 is formed in the top section 152 of the blank 100 using
7 conventional techniques. A first ferrite or magnetic region 156 is formed on the
8 perimeter and adjacent to aperture 140. The method of forming the ferrite or magnetic
9 regions will be discussed below. An exemplary flap 120 is formed in a top section 150 of
10 blank 100. The flap is formed by making cuts along section 150 using conventional
11 methods. A second ferrite or magnetic region 126 is formed on a side of flap 120
12 opposite the first ferrite region 156. Flap 120 is shown with optional tab 122 to assist
13 with opening and closing the container 105 via the flap 120. The tap 122 can be formed
14 from cutting a portion of the blank 100 using conventional methods. The container 105 of
15 Figure 2 can be formed using the blank of Figure 1 using conventional techniques well
16 known in the art.

17 If container 105 stores perishable items such as breakfast cereal, then the re-
18 closure system (flap and opening with first and second magnetic region) must be
19 arranged or dimensioned to provide adequate barrier properties, such as moisture, air, and
20 vermin barriers for the container 105. By properly designing the ferrite or magnetic
21 regions, the conventional membrane for the perishable products can be eliminated. In an
22 exemplary embodiment, the blank 100 for the container 105 is coated with polymeric
23 material to create the desired barrier properties. Exemplary coatings include extrusion

1 coating of various polyethylenes onto the side of the blank 100 which will form the
2 interior of the container 105. To protect against tampering with the container 105, the
3 flap 120 can have a tamper seal or tear off strip (not shown), surrounding the flap 120
4 which is broken or removed when the container 105 is initially opened. Exemplary
5 tamper seals are made from paper or cellophane, although a wide-range of tamper proof
6 measures are encompassed by the scope of the invention.

7 The formation of the ferrite or magnetic regions, hereinafter referred to as ferrite
8 regions, may be accomplished by several exemplary methods. In a first exemplary
9 embodiment, the ferrite regions are formed from magnetic gaskets to form a re-closure
10 system as discussed above. The magnetic gaskets are made from commercially available
11 flexible magnetic sheeting, such as magnetic sheets made by Plastiform Division of
12 Arnold Engineering. Magnetic sheets of this type are conventionally used for magnetic
13 tags, signs, "refrigerator magnets," and the like. The magnetic sheets are pre-cut prior to
14 placement on the blank 100 to the desired shape and size. The magnetic gaskets are then
15 bonded to the flap or container blank using a conventional labeling machine adapted for
16 this purpose.

17 Various types of labeling equipment are used in the packaging industry to apply
18 labels to almost any type container, with a high degree of placement accuracy and at
19 production rates of many thousands of containers/hour. The magnetic gaskets may have
20 pre-applied pressure sensitive adhesive ("PSA") or a gluer can be used to apply adhesive,
21 in the desired pattern, to each container blank. Application of the magnetic gaskets may
22 be applied "inline" on the same continuous production line that prints, cuts, and scores
23 the base substrate web in form to produce individual carton blanks.

1 According to this embodiment the magnetization pattern (spatial extent of the
2 zonal bands of magnetization and their polarity) are exactly the same for the flap
3 magnetic strip and the container opening magnetic strip. For example, if spatial
4 arrangement of the opposing magnetic gaskets is exactly the same but with opposite
5 magnetic polarity, the magnetic force produced between the flap and the container will be
6 repulsive rather than attractive. Thus, maximum attractive force between the flap and
7 container will be produced only if the magnetization zonal patterns of the two regions are
8 “in register” and aligned.

9 In order to achieve accurate magnetic register with stacked blanks, and also to
10 avoid possible production problems, such as feeding problems, i.e., two or more
11 container blanks sticking together, prior to the cartons erection and filling, magnetization
12 of the magnetic gaskets may be done on the container filling line itself. Accurate
13 magnetic pole registration is possible on a carton filling line by using a jig that keys in, or
14 counter-fits to the external contour of the carton blank to precisely locate and align the
15 blank relative to the magnetizing fixture. The magnetizing fixture poles (assuming a
16 linear magnetization pattern) are either exactly parallel or perpendicular to the folding
17 axis of the closure flap. For cartons made from a single blank whose closure flap is
18 directly attached to the body of the carton by a score-fold, the latter orientation will in
19 practice yield the most consistent result, as the effect of small flexional displacements at
20 the folding score is thus obviated.

21 The holding strength of flat, sheet-form magnets is a function of the number of
22 poles-per-inch of the magnetization pattern, where a fine pattern (having a large number
23 of poles/inch) increases the holding strength of a magnet, all else (magnet composition

1 and thickness) equal. Choice of a poles/inch value for a magnetic closure will thus be a
2 tradeoff between a desirable high holding strength and the degree to which it is possible
3 to maintain magnetic register. A value of ~10-12 poles/inch should strike a satisfactory
4 balance, and this value is in fact within a range conventionally used. State of the art
5 magnetizers currently can have up to 18 poles/inch, and 50 poles/inch is said to be
6 attainable. This latter value suggests an alternative approach to achieving magnetic polar
7 register.

8 Two sheet-type magnets that are magnetized at 50 poles/inch will re-establish
9 register each time they are displaced relative to each other by 1/25th of an inch in a
10 shearwise fashion (and in a direction perpendicular to their lines of polarization). If the
11 hinge point between the closure flap and carton is made flexible and compliant, the flap
12 will automatically position itself so that its magnetization pattern is in register with that
13 of the carton. One embodiment of this approach for a paperboard container would be to
14 have a separate closure flap joined to the container via a strip of polymeric material in
15 thin sheet form, such as any type plastic film conventionally used to make so-called
16 flexible packaging, i.e., polyethylene. Now, the most advantageous orientation of a
17 (linear) magnetization pattern on the flap and container would be to have the lines
18 parallel to the folding axis. Then, width of the film that bridges the gap between the flap
19 and container to form a hinge would only need to be on the order of a small multiple of
20 the 1/25 inch "repeat length" just described--say 0.1 to 0.125 inches. For illustration
21 purposes, the techniques described above yield for a flap design of Figures 1 and 2 a
22 tensile opening force (applied to the tab on the end of the flap) equal to approximately

1 0.25 lbf. This is enough resistance to prevent accidental opening due to the weight of the
2 contents, should the box fall over or be laid down on its side.

3 An approach that by-passes the necessity of providing accurate polar registration
4 between magnetic gaskets upon the carton body and flap is to magnetize only one of the
5 gaskets. The opposing non-magnetized gasket is made from a magnetically receptive
6 material such as "Rubber Steel" ® made by Magnum Magnetics, Inc. A magnetically
7 receptive paint (Magic Wall™ latex) is made by Kling Magnetics, Inc. under license of
8 U.S. patents #5,609,688 and #5,843,329. From a functional standpoint it does not matter
9 which surface is magnetically receptive, i.e, the flap or the container. However, various
10 product promotional purposes, such as advertisement, collectibles, product data, etc,
11 could be served if the flap's gasket is magnetized and easily removable. As previously
12 mentioned, magnetization of a single magnetic gasket would likely be done later on the
13 filling line, to avoid possible feeding problems with stacked blanks.

14 An alternative to using a polymer-based, flexible magnetic sheet to form a carton
15 closure is to print magnetic regions directly onto the container blank. In an exemplary
16 print method, the ferrite particles are mixed with a binder, which can be a latex-, oil-, or
17 lacquer-based paint, ink, or coating, for subsequent printing or coating application to the
18 paperboard.

19 Magnetization is then done by conventional means (application of an external
20 magnetic field of strength sufficient to align the "domains" of the magnetic filler
21 particles). Strength of the magnet thus produced is a function of the thickness of the
22 coated or extruded magnetic layer, magnetic particle packing density within the binder,
23 and the particular magnetic compound chosen for use.

1 An exemplary magnetic region forming technique is a screen printing press
2 method. Screen printing has an advantage since the amount of ink that can be applied in
3 terms of ink deposition thickness is much greater than other printing processes (e.g.
4 rotogravure, flexographic, offset lithography). Magnetic holding strength is known to be
5 a strong function of the volumetric packing density of ferrite that composes a magnetic
6 layer. Of the three types (ultraviolet cured, heat cured, and solvent based) ink used in the
7 experiments, solvent based inks gave the highest volume fractions of ferrite, and
8 consequent best magnetic performance. This is first of all because the solvent based ink
9 had a lower initial viscosity than the other types ink, so that more ferrite could be mixed
10 with the ink before viscosity of the mixture increased to a point beyond which printing is
11 possible. Secondly, and very important, much of the initial volume of the ink is lost
12 through solvent evaporation: the drying and curing process effectively acts to concentrate
13 the volume fraction of ferrite in the printed layer. An additional process step is
14 necessary, however, to obtain maximum ferrite packing density. Solvent evaporation
15 leaves air voids in the ferrite/ink mixture, so it is necessary to compact the printed layer
16 when it is yet in a semi-cured, plastic state. This can be done by passing the printed
17 substrate through one or more lightly loaded (less than 20 kN/meter ~ 114 lbf/lineal inch)
18 "nips" formed between hard rolls covered with a suitable release-type coating (Teflon®,
19 for example). By this means, thickness of a solvent-based, printed ferrite layer can be
20 decreased (and its density increased) by a factor of two, and volumetric fractions of
21 ferrite in excess of 75% can be attained.

22 Magnetic properties of the printed layer may be further enhanced by creating a
23 strong magnetic field within the nip itself, so as to induce a degree of anisotropy within

1 the magnetic layer (a purely anisotropic magnet is one whose individual magnetic
2 domains share a common, parallel orientation). A magnetic field having the desired
3 orientation (perpendicular to the web) may be created within the nip zone by constructing
4 the rolls from a ferromagnetic material (iron or steel, for example), and installing
5 electromagnetic coils on the side of each roll opposite the nip. This approach is
6 potentially most advantageous for so-called "high energy" ferrites, whose individual
7 particles are intentionally made to be a single magnetic domain--within the industry, this
8 is termed "uniaxial crystalline anisotropy." The unipolar magnetic field of each
9 individual particle tends to orient itself parallel to the field imposed within the roll nip.
10 An additive effect of the roll nip is its ability to mechanically orient those types ferrite
11 powder whose particulate morphology is intentionally manipulated during manufacture to
12 create plate-shaped particles having a length and width greater than the thickness--fluid
13 shear within the nip zone acts to mechanically orient the platelike particles parallel to the
14 plane of the web. Magnetic orientation of these ferrites is typically made to be normal to
15 the plane of the particle, so the net (and intended) effect of particle orientation induced by
16 both magnetic and mechanical means is to create a non-isotropic magnet. These
17 techniques form part of the conventional art of manufacturing flexible polymer-based
18 magnets, but are here extended to the potential production of magnets created by the
19 printing ferrite ink.

20 An exemplary ferrite region was formed using an ink (Coates Screen Gloss Vinyl
21 C-99 mixing clear) chosen for its high degree of mechanical flexibility when cured.
22 Weight proportions of six parts ferrite, one part mixing clear, and 2.4 parts reducer were
23 combined to make the ferrite ink. The mixing clear contains approximately 70% volatile

1 solvent and 30% binder by weight: the above proportions provide a mixture that can be
2 printed and cured to contain at least 75% ferrite by volume. Use of a 60 mesh screen, a
3 200 micron emulsion, and a 60 durometer squeegee yielded a per pass dried film
4 thickness of approximately 7 mils after being consolidated in a roll nip. Ferrite layers
5 .014 inches thick were produced by overprinting (double thickness) and then were
6 magnetized at 18 poles/inch. Magnetic holding strength was 1.3 ounces/square inch,
7 about 30% that of a typical, .020 inch thick flexible bonded magnet.

8 One problem with producing magnetic zones by direct printing of ferrite ink onto
9 a substrate is the extremely heavy ink application rate required. A typical ink thickness,
10 or laydown, of screen printed graphic designs for packaging applications is ~.0005
11 inches, or 1/30 the amount cited above. This means that drying and curing of a screen
12 printed magnetic surface is presently a production bottleneck. Even with compact
13 designs for forced air dryers (vertical units with serpentine web runs) are available,
14 drying rate limitations inherent to thick coatings would dictate layers as thick as 0.015
15 inches would have to be printed using multiple print stations. Thus direct printing
16 approaches require expensive dryers and have slow production rates.

17 Figures 3 and 4 illustrate another top flap container arrangement. Blank 200 has
18 two top sections 252, 253 connected by fold line 260. An aperture 240 is formed in top
19 section 252. A first magnetic region 256 is formed on top section 252 and a second
20 magnetic 226 is formed on top section 253. Blank 200 is folded as described above in
21 Figures 1 and 2 to form container 205 (Figure 4).

1 Figures 5 and 6 illustrate another top flap container arrangement. Blank 300 has
2 four top sections 350, 320, 352, 353. An aperture 340 is formed in top section 352. A
3 first magnetic region 356 is formed on top section 352 and a second magnetic 326 is
4 formed on flap 320. Blank 300 is folded as described above in Figures 1 and 2 to form
5 container 305 (Figure 6). Flap 320 is connected to body section 330 along hinge line
6 370.

7 ↓
7 Figures 7 and 8 illustrate another top flap container arrangement. Blank 400 has
8 three top sections 452, 420, 454. An aperture 440 is formed in top sections 452, 420. A
9 first magnetic region 456 is formed on top section 420 and a second magnetic 426 is
10 formed on top section 420. Blank 400 is folded as described above in Figures 1 and 2 to
11 form container 405 (Figure 8). Top section 420 is connected to body section 340 along
12 hinge line 470. Top section 420 is cut along line 472 to form a flap that covers aperture
13 440.

14 Figures 9 and 10 illustrate a slide flap container arrangement. Blank 500 has four
15 top sections 550, 520, 552, 554. An aperture 540 is formed in main body sections 532.
16 A first magnetic region 556 is formed on main body section 532 and a second magnetic
17 region 526 is formed on top section 520. The second magnetic region 526 is formed on
18 an opposite side of blank 500 from the first magnetic region 556. Blank 500 is folded as
19 described above in Figures 1 and 2 to form container 505 (Figure 10). Top section 552 is
20 connected to body section 534 along hinge line 546. Top section 520 is cut along line
21 553 to form a flap 520 that covers aperture 540. Flap 520 is connected to top section 550
22 along hinge line 542.

1 Figures 11 and 12 illustrate a second embodiment of a slide flap container
2 arrangement. Blank 600 has four top sections 650, 620, 652, 654. An aperture 640 is
3 formed in main body sections 632. A first magnetic region 656 is formed on main body
4 section 632 and a second magnetic region 626 is formed on top section 620. The second
5 magnetic region 626 is formed on the same side of blank 600 as the first magnetic region
6 656. Blank 600 is folded as described above in Figures 1 and 2 to form container 605
7 (Figure 12). Top section 652 is connected to body section 634 along hinge line 646. Top
8 section 620 is cut along line 653 to form a flap 620 that covers aperture 640. Flap 620 is
9 connected to top section 650 along hinge line 642.

10 It is to further be understood that the opening, flap, and magnetic regions of
11 container formed according to the invention can have numerous arrangements,
12 configurations, designs, locations, and dimensions within the scope of the invention. In
13 addition the body of the container and flap can be formed from a single or a plurality of
14 blanks using techniques well know in the art to form containers. It is to further be
15 understood that the term ferrite or magnetic region encompasses a wide range of material
16 capable of either forming a sufficiently strong magnetic field or being sufficiently
17 magnetically receptive to allow a sufficiently strong enough magnetic attraction to form
18 between the flap and the container body.

19 Once given the above disclosure, many other features, modifications or
20 improvements will become apparent to the skilled artisan. Such features, modifications
21 or improvements are, therefore, considered to be a part of this invention, the scope of
22 which is to be determined by the following claims.
